B卷-00P Midterm

Problem A: Class (20%)

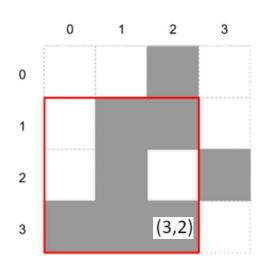

Define a class called Odometer that will be used to track fuel and mileage for an automotive vehicle. Include private member variables to track the miles driven and the fuel efficiency of the vehicle in miles per gallon. The class should have a constructor that initializes these values to zero. Include a member function to reset the odometer to zero miles, setting the fuel efficiency=5, a member function that accepts miles driven for a trip and adds it to the odometer's total, and a member function that returns the number of gallons of gasoline that the vehicle has consumed since the odometer was last reset. Use your class with a test program that creates several trips with different fuel efficiencies.

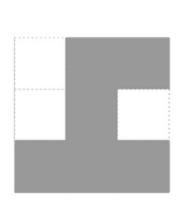

Example:

```
Enter number of miles:
30
After 30 miles 6 gallon(s) is used
Enter additional number of miles:
5
After 5 miles 7 gallon(s) is used
```

Problem B: Dynamic Array (20%)

You get one image(N*N) as the main image and several small images(M*M). M can be any number that N>M>1. Your task is to find the position where the small image is similar to a part of the main image, and output the index which is the down right. (you don't need to rotate the small image, and there must have one and only one fit position)

```
testcase(the texts between() are not in testcase)
4(N=4) 2(2 small images)
0010
0110
0101
1110
3(M=3)
011
010
111
2(M=2)
10
10
output:
32
```

Problem C: Overloading (25%)

There are three Complex numbers in the <u>test.txt</u>. And you have <u>one class named Complex</u>, and there are <u>two private members</u> called <u>real and imagine</u>.

In this question, you are asked to <u>use overloading " * "</u> to multiply first number and second number, and then <u>use overloading " - "</u> to add the result from "*" and the third number. Finally, <u>using overloading " cout "</u> to output the number on the terminal.

```
For example: first number: 1-2i, second number: -9+8i, third number: -5-5i \Rightarrow (1-2i)*(-9+8i) = ((1*-9)+(-2*8)*-1)+((1*8)+(-2*-9))i = 7+26i \Rightarrow (7+26i)-(-5-5i) = 12+31i \Rightarrow Terminal: The answer is 12+31i Another example: first number: 5-3i, second number: -9+2i, third number: 6+6i \Rightarrow (5-3i)*(-9+2i) = (5*-9+(-3*2)*-1)+((5*2)+(-3*-9))i = -39+37i \Rightarrow (-39+37i)-(6+6i)=-45+31i \Rightarrow Terminal: The answer is -45+31i
```

Problem D: Pointer (25%)

The information in the 5*5 maze is monster's number. There will be a 25*2 monster information here, and the number of the monster corresponds to this 25*2 matrix seat.

You will play a player to explore in this maze. The player's initial HP is 80, the initial experience value is 0, and the initial level is 1, and the player's initial position is at (0,0).

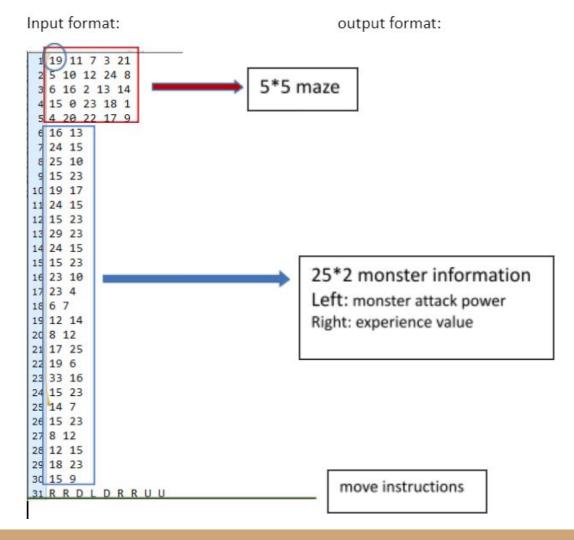

In this program you need to read the file, in the file will give you 5*5 maze information, and give you 25*2 monster attack power and experience value, and will give you move instructions, U stands for up, D stands for down, L stands for left, R stands for right.

To defeat a monster, the player's HP will be deducted from the monster's attack power, and the experience value will be added to the experience value given by the monster. When the player's experience value reaches 50, the player will be upgraded. When the player is upgraded, the blood volume will return to 80. The experience value will return to zero, and output at each step, the output format is as follows.

(If the monster's ATK is greater than the player's HP, output "DEAD" and end the program)

(There is no need to calculate the position (0,0) at the beginning)

(The movement command will not exceed the maze, so there is no need to judge that it is beyond the boundary.)

step 1: level:0 hp:57 exp:4 step 2: level:0 hp:28 exp:27 step 3: level:0 hp:22 exp:34 DEAD Input: output:

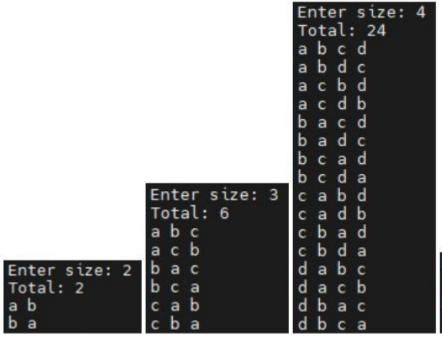

```
step 1:
level:0 hp:72 exp:12
step 2:
level:0 hp:49 exp:22
step 3:
level:0 hp:33 exp:35
step 4:
level:0 hp:27 exp:42
step 5:
level:1 hp:80 exp:0
step 6:
level:1 hp:65 exp:23
step 7:
level:1 hp:53 exp:37
step 8:
level:1 hp:38 exp:46
```

Maze:				
11	19	2	3	31
14	10	7	24	9
6	0	12	13	5
15	16	23	18	1
20	4	22	17	8

Position(0,0)

Problem E: Recursion (30%)

Print the permutations of size n (1<=n<=26) with recursive function.

Enter size: 0 Invalid size. Enter size: 27 Invalid size.
